TECHNOTE
"List" data type

A "List" data type field forces the users to choose between a list of values that can be saved to the database, rather than being able to manually type them.

This eases the record insertion task and makes it less error prone, by avoiding the typing of duplicated data.
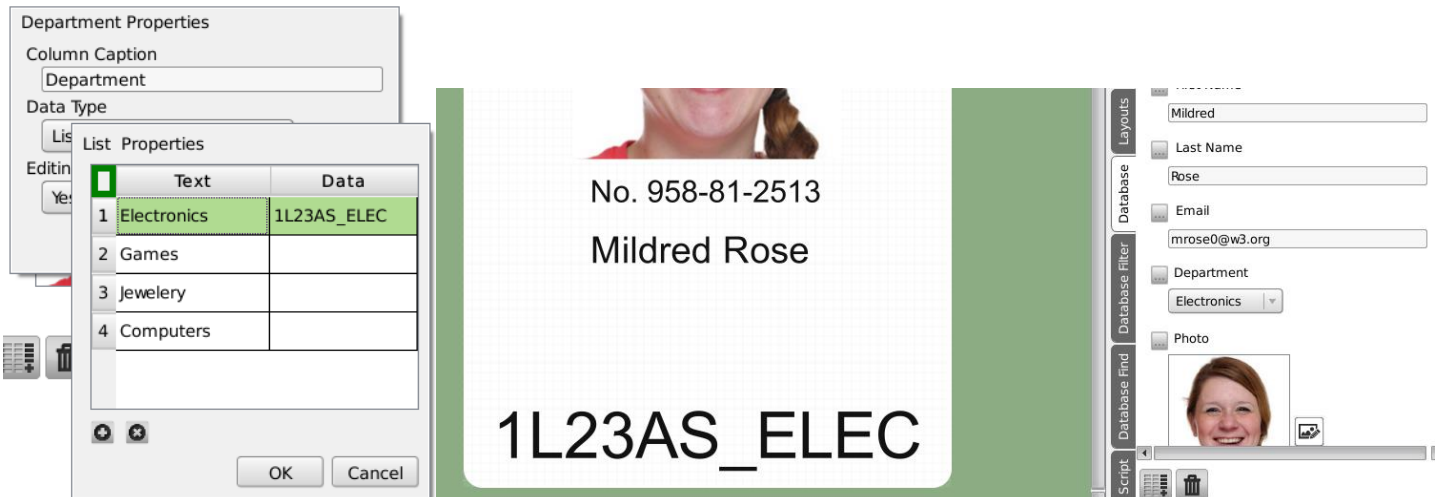

To configure a List field in our software, click in the column's Properties button and choose the "List" option.
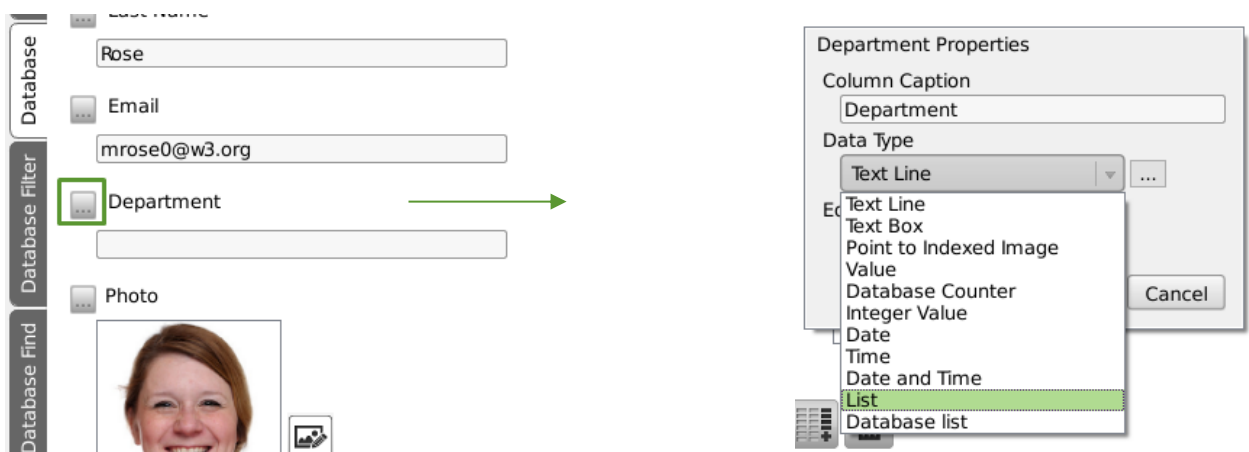

Then, click on the Properties button of the "List" data type and fill in the table according with the following instructions:

- Text: corresponds to the value that is visible for selection, on the List field of your card project
- Data: corresponds to the value that will be saved in the database source and displayed on the layout design.

As illustrated in the screenshot below, the operator will only see "Electronics" but the value "1L23AS_ELEC" will be saved in the database and displayed in the layout.
